

# Modbus on Senseair S88

## 1. General

Modbus is a simple, open protocol for both PLC and sensors. Details on Modbus can be found on [www.modbus.org](http://www.modbus.org).

This specification is based on the specification of Modbus implementation on aSense, eSense and Sensor Core and aims to support backwards compatibility with them. The differences between the Modbus specification [1] and the default implementation in the sensor are listed in this document.

## General overview of protocol and implementation in the sensor

### Master – slave:

Only master can initiate a transaction. The sensor is a slave and will never initiate communication. The host system initiates transactions to read CO<sub>2</sub> value from the corresponding register. The host system shall also check status of the sensor periodically (e.g. every two (2) seconds) in order to determine if it is running without faults detected.

### Packet identification:

Any message (packet) starts with a silent interval of 3.5 characters. Another silent interval of 3.5 characters marks message end. Silence interval between characters in the message needs to be kept less than 1.5 characters.

Both intervals are from the end of Stop-bit of previous byte to the beginning of the Start-bit of the next byte.

### Packet length:

According to the Modbus specification [1], the packet length shall be maximum 252 bytes including address and CRC. **Packets of larger size are rejected without any answer from sensor**

### Modbus data model:

There are four (4) primary data tables (addressable registers), which may overlay:

- Discrete Input (read only bit).
- Coil (read / write bit).
- Input register (read only 16 bit word, interpretation is up to application).
- Holding register (read / write 16 bit word).

**Note: The sensor does not support bitwise access of registers.**

### Exception responses:

Slave will send answer to the master only in the case of valid message structure. Nevertheless, it can send exception response because of detection of:

- Invalid function code.
- Invalid data address (requested register doesn't exist in given device).
- Invalid data.
- Error in execution of requested function.

## 2. Byte transmission.

RTU transmission mode is the only mode supported by the sensor.

### 2.1. Byte format:

The format for each byte in RTU mode differs between the sensor default configuration and the description on page 12 of Modbus over serial line specification [2].

|                | Modbus over serial line specification [2] |               | Sensor default configuration                            |
|----------------|---|---------------|---|
| Coding system  | 8-bit binary                              |               | 8-bit binary  |
| Bits per byte: | 1 start bit                               |               | 1 start bit   |
| Data bits      | 8 data bits, least significant bit first  |               | 8 data bits, least significant bit first                |
|                | 1 bit for even parity                     | No parity bit | NO parity bit   |
|                | 1 stop bit                                | 2 stop bits   | 1 stop bit for receiving<br>2 stop bits at transmission |

Table 1: Byte format differences

Implementation of 1 stop bit on receive and 2 stop bits at transmit provides compatibility with masters using both 1 and 2 stop bits.

### 2.2. Baud rate (data signalling rate)

9600 bps and 19200 bps are required baud rates and required default baud rate according to MODBUS over serial line specification [2], page 20, is 19200 bps.

Senseair S88 supports 9600 baud rate only.

### 2.3. Physical layer:

The sensor provides CMOS logical levels RxD and TxD lines for serial transmission. It's up to the system integrator to use them for direct communication with master processor or for connection to RS-232 or RS-485 drivers. Sensor has support for R/T control line.

Communication lines are fed directly to the micro-controller of the sensor. Please refer to technical description for electrical specifications of particular model.

### 3. Modbus registers on sensor.

The Modbus registers are mapped in memory, both RAM and EEPROM of the sensor. Mapping is interpreted by sensor firmware at command reception.

Presently, the following restrictive decisions are made:

1. Read only and read / write registers are not allowed to overlay.
2. Bit addressable items (i.e. Coils and Discrete inputs) will not be implemented.
3. Only write single register functional codes are implemented. Multiple write functional codes are not planned for implementation.
4. The total number of registers should be limited. Present decision is to limit number of input registers to 32 and number of holding registers to 33.
5. Larger amount of data should be transferred as file. It is not implemented at the current stage of development.

Maps of registers (All registers are 16 bit word) are summarised in Table 3 and Table 4. Associated number is Modbus register number: Register address is calculated as (register number - 1

| HR22 | 21 | OUT1 Override         | Use to override "PWM Output" variable to test PWM output   |
| HR23 | 22 |                       | Reserved, returns "illegal data address" exception   |
| HR24 | 23 |                       | Reserved, returns "illegal data address" exception   |
| HR25 | 24 |                       | Reserved, returns "illegal data address" exception   |
| HR26 | 25 |                       | Reserved, returns "illegal data address" exception   |
| HR27 | 26 | Default pressure      | EEPROM mapped, optional. Use 0 or negative value to disable pressure compensation. Load on start-up into HR4_Pressure. LSB - 0.1hPa<br>Pressure compensation disabled by default   |
| HR28 | 27 | Static IIR config     | IIR filter configuration: 0 - filtering disabled, 1 to 16 - static filter parameter, 255 - factory default settings.<br><b>Note:</b> If value of the variable is not equal to 255, ABC functionality will omit environment gas stability checks. |
| HR29 | 28 |                       | Reserved, returns "illegal data address" exception   |
| HR30 | 29 |                       | Reserved, returns "illegal data address" exception   |
| HR31 | 30 |                       | Reserved, returns "illegal data address" exception   |
| HR32 | 31 | ABC Period            | ABC Period in hours <sup>8</sup> EEPROM mapped   |
| HR33 | 32 | ABC Target            | ABC target in concentration bins. EEPROM mapped  |

Table 3: Holding Registers

<sup>6</sup> – Reserved CIs return 0.

<sup>7</sup> – Special Command Register is write-only.

<sup>8</sup> – Writing to ABC\_Period zero value suspends ABC function. ABC samples and ABC time counting will not be reset. To resume ABC function with prior ABC samples and ABC time write to ABC\_Period non-zero value.

**Note:** The new settings in the registers (excluding HR1-HR3, HR22) applies only after sensor restart

**Note:** Holding registers are EEPROM mapped parameters (excluding HR1-HR4, HR22), this means that too frequent writes to these registers will lead to a EEPROM corrupt. Total number of EEPROM write cycles should be less than 10000. When writing multiple registers in one sequence then this write cycle will be counted as just one write cycle out of the 10000 that are allowed writes to the EEPROM. If sensor is powered down/reset when EEPROM write operations are ongoing it may result in corrupt parameters. Please wait at least 180ms before powering down/reset sensor after holding registers change (or wait sensor response on corresponding Modbus request).

## 4. Serial line frame and addressing.

### 4.1. Serial line frame

Modbus over serial line specification [2] distinguishes Modbus Protocol PDU and Modbus serial line PDU in the following way (RTU mode only is under consideration):

### 4.2. Addressing rules

Addressing rules are summarised in the table:

| Address         | Modbus over serial line V1.0 | Senseair S88 Sensor      |
|-----------------|------------------------------|--------------------------|
| 0               | Broadcast address            | Broadcast address        |
| From 1 to 247   | Slave individual address     | Slave individual address |
| From 248 to 253 | Reserved                     | Nothing <sup>1)</sup>    |
| 254             | Reserved                     | “Any sensor”             |
| 255             | Reserved                     | Nothing <sup>1)</sup>    |

Table 4: Summarised addressing rules

Notes:

1. “Nothing” means that sensor doesn’t recognise Modbus serial line PDUs with this address as addressed to the sensor. Sensor does not respond.
2. “Any sensor” means that any sensor with any slave individual address will recognise serial line PDUs with address 254 as addressed to them. They will respond. So that this address is for production / test purposes only. It must not be used in the installed network. This is a violation against the Modbus specification [1].

### 4.3. Broadcast address

Modbus specification [1] requires execution of all write commands in the broadcast address mode.

Current status for the sensor: Broadcast commands are implemented.

## 5. Bus timing.

| Parameter         | Min | Type | Max | Units |
|-------------------|-----|------|-----|-------|
| Response time-out |     |      | 180 | msec  |

Table 5: Bus timing

“Response time-out” is defined to prevent master (host system) from staying in “Waiting for reply” state indefinitely. Refer to page 9 of MODBUS over serial line specification [2].

For slave device “Response time-out” represents maximum time allowed to take by “processing of required action”, “formatting normal reply” and “normal reply sent” alternatively by “formatting error reply” and “error reply sent”, refer to the slave state diagram on page 10 of the document mentioned above.

**Note:** Due to hardware limitations, probability for end-customers to get the response timeout on a Modbus request in normal conditions could be 0.000007. For reliable sensor reading, the host shall use retries in communication.

## 6. Function codes descriptions (PUBLIC).

Description of exception responses

If the PDU of the received command has wrong format:

No Response PDU, (sensor doesn't respond)

If Function Code isn't equal to any implemented function code:

Exception Response PDU.

|  |        |                      |
|--|--------|----------------------|
| Function code                            | 1 byte | Function Code + 0x80 |
| Exception code = <i>Illegal Function</i> | 1 byte | 0x01                 |

If one or more of addressed Registers is not assigned (register is reserved or Quantity of registers is larger than maximum number of supported registers):

Exception Response PDU.

|  |        |                      |
|--|--------|----------------------|
| Function code                                | 1 byte | Function Code + 0x80 |
| Exception code = <i>Illegal Data Address</i> | 1 byte | 0x02                 |

### 6.1.01 (0x01) Read Coils (one bit read / write registers).

Not implemented.

### 6.2.02 (0x02) Read Discrete Inputs (one bit read only registers).

Not implemented.

### 6.3.03 (0x03) Read Holding Registers (16 bits read / write registers).

Refer to Modbus specification [1].

Address of Modbus Holding Registers for 1-command reading is limited in range 0x0000..0x0020.

Request PDU

|                          |        |             |
|--------------------------|--------|-------------|
| Function code            | 1 byte | <b>0x03</b> |
| Starting Address Hi      | 1 byte | Address Hi  |
| Starting Address Lo      | 1 byte | Address Lo  |
| Quantity of Registers Hi | 1 byte | Quantity Hi |
| Quantity of Registers Lo | 1 byte | Quantity Lo |

Response PDU

|                |              |             |
|----------------|--------------|-------------|
| Function code  | 1 byte       | <b>0x03</b> |
| Byte Count     | 1 byte       | 2 x N*      |
| Register Value | N* x 2 bytes |             |

\* N = Quantity of Registers

If Address>0x0020 or (Address + Quantity)>0x0020:

Exception Response PDU.

|  |        |             |
|--|--------|-------------|
| Function code                                | 1 byte | <b>0x83</b> |
| Exception code = <i>Illegal Data Address</i> | 1 byte | 0x02        |

If Quantity=0 or Quantity>0x007D:

Exception Response PDU.

|  |        |             |
|--|--------|-------------|
| Function code                              | 1 byte | <b>0x83</b> |
| Exception code = <i>Illegal Data Value</i> | 1 byte | 0x03        |

#### 6.4.04 (0x04) Read Input Registers (16 bits read only registers).

Refer to Modbus specification [1].

Address of Modbus Input Registers for 1-command reading is limited in range 0x0000..0x001F.

Request PDU

|                          |        |             |
|--------------------------|--------|-------------|
| Function code            | 1 byte | <b>0x04</b> |
| Starting Address Hi      | 1 byte | Address Hi  |
| Starting Address Lo      | 1 byte | Address Lo  |
| Quantity of Registers Hi | 1 byte | Quantity Hi |
| Quantity of Registers Lo | 1 byte | Quantity Lo |

Response PDU

|                |              |             |
|----------------|--------------|-------------|
| Function code  | 1 byte       | <b>0x04</b> |
| Byte Count     | 1 byte       | 2 x N*      |
| Register Value | N* x 2 bytes |             |

\* N = Quantity of Registers

If Address>0x001F or (Address + Quantity)>0x0020:

Exception Response PDU.

|  |        |             |
|--|--------|-------------|
| Function code                                | 1 byte | <b>0x84</b> |
| Exception code = <i>Illegal Data Address</i> | 1 byte | 0x02        |

If Quantity=0 or Quantity>0x007D:

Exception Response PDU.

|  |        |             |
|--|--------|-------------|
| Function code                              | 1 byte | <b>0x84</b> |
| Exception code = <i>Illegal Data Value</i> | 1 byte | 0x03        |

#### 6.5.06 (0x06) Write Single Register (16 bits read / write register).

Refer to Modbus specification [1].

Address of Modbus Holding Registers for 1-command reading/writing is limited in range 0x0000..0x0020.

Request PDU

|                     |        |             |
|---------------------|--------|-------------|
| Function code       | 1 byte | <b>0x06</b> |
| Starting Address Hi | 1 byte | Address Hi  |
| Starting Address Lo | 1 byte | Address Lo  |
| Register Value Hi   | 1 byte | Value Hi    |
| Register Value Lo   | 1 byte | Value Lo    |

Response PDU (is an echo of the Request)

|                     |        |            |
|---------------------|--------|------------|
| Function code       | 1 byte | 0x06       |
| Starting Address Hi | 1 byte | Address Hi |
| Starting Address Lo | 1 byte | Address Lo |
| Register Value Hi   | 1 byte | Value Hi   |
| Register Value Lo   | 1 byte | Value Lo   |

If Address > 0x0020:

Exception Response PDU.

|  |        |      |
|--|--------|------|
| Function code                                | 1 byte | 0x86 |
| Exception code = <i>Illegal Data Address</i> | 1 byte | 0x02 |

### 6.6.16 (0x10) Write Multiple Registers (16 bits read / write register).

16 bits read/write register.

Refer to Modbus specification [1].

Address of Modbus Holding Registers for 1-command reading/writing is limited in range 0x0000..0x0020.

Request PDU

|                          |               |                |
|--------------------------|---------------|----------------|
| <b>Function code</b>     | <b>1 byte</b> | <b>0x10</b>    |
| Starting Address Hi      | 1 byte        | Address Hi     |
| Starting Address Lo      | 1 byte        | Address Lo     |
| Number of Register Hi    | 1 byte        | Value Hi       |
| Number of Register Lo    | 1 byte        | Value Lo       |
| The Number of Data Bytes | 1 byte        | 2 x N*         |
| Register Value to Write  | 2 x N* bytes  | Value to write |

\* N = Quantity of Registers

Response PDU (is an echo of the Request)

|                               |               |             |
|-------------------------------|---------------|-------------|
| <b>Function code</b>          | <b>1 byte</b> | <b>0x10</b> |
| Starting Address Hi           | 1 byte        | Address Hi  |
| Starting Address Lo           | 1 byte        | Address Lo  |
| Number of Register written Hi | 1 byte        | Value Hi    |
| Number of Register written Lo | 1 byte        | Value Lo    |

If Address is out of range:

Exception Response PDU

|  |               |             |
|--|---------------|-------------|
| <b>Function code</b>                         | <b>1 byte</b> | <b>0x90</b> |
| Exception code = <i>Illegal Data Address</i> | 1 byte        | 0x02        |

## 43 / 14 (0x2B / 0x0E) Read Device Identification.

Refer to Modbus specification ...

The sensor only supports Read Device ID code 4, individual access.

Objects 0x00 ..0x02 (basic identification) are available (see table)

| Object ID      | Object Name / Description  | Type                | Modbus status | Category | Implementation status |
|----------------|--|---------------------|---------------|----------|-----------------------|
| 0x00           | Vendor Name  | ASCII string*       | Mandatory     | Basic    | Implemented           |
| 0x01           | ProductCode  | ASCII string*       | Mandatory     | Basic    | Implemented           |
| 0x02           | MajorMinorRevision   | ASCII string*       | Mandatory     | Basic    | Implemented           |
| 0x03           | VendorUrl  | ASCII string*       | Optional      | Regular  | Not Implemented       |
| 0x04           | ProductName  | ASCII string*       | Optional      | Regular  | Not Implemented       |
| 0x05           | ModelName  | ASCII string*       | Optional      | Regular  | Not Implemented       |
| 0x06           | UserApplicationName  | ASCII string*       | Optional      | Regular  | Not Implemented       |
| 0x07..<br>0x7F | Reserved   |                     |               |          |                       |
| 0x80           | Memory map version   | 1 byte<br>unsigned  | Optional      | Extended | Not Implemented       |
| 0x81           | Firmware revision,<br>consists of:<br>Firmware type,<br>Revision Main,<br>Revision Sub | 3 bytes<br>unsigned | Optional      | Extended | Not Implemented       |
| 0x82           | Sensor serial number<br>(sensor ID)  | 4 bytes<br>unsigned | Optional      | Extended | Not Implemented       |
| 0x83           | Sensor type  | 3 bytes<br>unsigned | Optional      | Extended | Not Implemented       |

\*The ASCII strings are different for different models and firmware revision. Product Code is the sensors article number. As an example:

Vendor Name = "Senseair"

(length 8 bytes)

MajorMinorRevision = "1.00"

(length 4 bytes)

Product Code = "004-1-0100"

(length 10 bytes)

Firmware revision 1.00 and later example:

### Example: Read objects of category "Basic"

Request PDU, Object ID 0x00 to 0x02

|                     |        |                               |
|---------------------|--------|-------------------------------|
| Function code       | 1 byte | 0x2B                          |
| MEI Type            | 1 byte | 0x0E                          |
| Read Device ID code | 1 byte | 0x04 (individual access only) |
| Object ID           | 1 byte | 0x00..0x02                    |

Response PDU, Object ID 0x00 to 0x02

|                     |        |  |
|---------------------|--------|--|
| Function code       | 1 byte | 0x2B   |
| MEI Type            | 1 byte | 0x0E   |
| Read Device ID code | 1 byte | 0x04, same as in request                                   |
| Conformity level    | 1 byte | 0x81, basic identification for individual or stream access |
| More Follows        | 1 byte | 0x00   |
| Next Object ID      | 1 byte | 0x00   |
| Number of objects   | 1 byte | 0x01   |
| Object ID           | 1 byte | 0x00..0x02   |
| Object length       | 1 byte | 0x0B or 0x07 or 0x04 (see definition of ASCII strings)     |
| Object value        | n byte | Object Data  |

### If wrong MEI Type:

Exception Response PDU

|   |               |             |
|---|---------------|-------------|
| <b>Function code</b>                          | <b>1 byte</b> | <b>0xAB</b> |
| Exception code = <i>Illegal Function Code</i> | 1 byte        | 0x01        |

### If Object ID is not in range 0x00..0x03:

Exception Response PDU

|  |               |             |
|--|---------------|-------------|
| <b>Function code</b>                         | <b>1 byte</b> | <b>0xAB</b> |
| Exception code = <i>Illegal Data Address</i> | 1 byte        | 0x02        |

### If wrong Device ID:

Exception Response PDU

|  |               |             |
|--|---------------|-------------|
| <b>Function code</b>                       | <b>1 byte</b> | <b>0xAB</b> |
| Exception code = <i>Illegal Data Value</i> | 1 byte        | 0x03        |

Note: The exception response for function code 43 is implemented according to the RFC “RFC Non extended Exception code format of 43 Encapsulated Transport.doc” which is in status “Recommended for approval” at time of writing. This is in contrast with the Modbus specification [1] where the exception responses for function code 43 also have a MEI type field.

## 7. References

- [1] MODBUS Application Protocol Specification V1.1b
- [2] MODBUS over serial line specification and implementation guide V1.02

## 8. Appendix A: Application examples

Prerequisites for the application examples:

1. A single slave (sensor) is assumed (address "any sensor" is used).
2. Values in <..> are hexadecimal.

### 8.1. CO<sub>2</sub> read sequence:

The sensor is addressed as "Any address" (0xFE).

We read CO<sub>2</sub> value from IR4 using "Read input registers" (function code 04). Hence, Starting address will be 0x0003 (register number-1) and Quantity of registers 0x0001. CRC calculated to 0xC5D5 is sent with low byte first.

We assume in this example that by sensor measured CO<sub>2</sub> value is 400ppm\*.

Sensor replies with CO<sub>2</sub> reading 400ppm (400 ppm = 0x190 hexadecimal).

Master Transmit:

<FE> <04> <00> <03> <00> <01> <D5> <C5>

Slave Reply:

<FE> <04> <02> <01> <90> <AC> <D8>

\* Note that some future models in the Senseair S8 family of sensors may have a different scale factor on the ppm reading. The reading on these models is divided by 10 (i.e. when ambient CO<sub>2</sub> level is 400ppm the sensor will transmit the number 40). In this example the reply from one of these models would be 40 (= 0x28 hexadecimal).

### 8.2. Sensor status read sequence:

The sensor is addressed as "Any address" (0xFE).

We read status from IR1 using "Read input registers" (function code 04). Hence, Starting address will be 0x0000 (register number-1) and Quantity of registers 0x0001. CRC calculated to 0xC525 is sent with low byte first.

Sensor replies with status 0.

Master Transmit:

<FE> <04> <00> <00> <00> <01> <25> <C5>

Slave Reply:

<FE> <04> <02> <00> <00> <AD> <24>

### 8.3. Sensor status and CO<sub>2</sub> read sequence:

The sensor is addressed as "Any address" (0xFE).  
Here we read both status and CO<sub>2</sub> in one command by reading IR 1 to 4 using "Read input registers" (function code 04). Hence, Starting address will be 0x0000 (register number-1) and Quantity of registers 0x0004. CRC calculated to 0xC6E5 is sent with low byte first.  
We assume in this example that by sensor measured CO<sub>2</sub> value is 400ppm\*.

Sensor replies with status=0 and CO<sub>2</sub> value 400ppm (0x190 hexadecimal).

Master Transmit:

<FE> <04> <00> <00> <00> <04> <E5> <C6>

Slave Reply:

<FE> <04> <08> <00> <00> <00> <00> <00> <00> <01> <90> <16> <E6>  
                  | Status |                  | CO2 |

\* Note that some future models in the Senseair S88 family of sensors may have a different scale factor on the ppm reading. The reading on these models is divided by 10 (i.e. when ambient CO<sub>2</sub> level is 400ppm the sensor will transmit the number 40). In this example the reply from one of these models would be 40 (= 0x28<sub>16</sub>).

## 8.4. Background calibration sequence:

The sensor is addressed as “Any address” (0xFE).

1. Clear acknowledgement register by writing 0 to HR1. Starting address is 0x0000 and Register value 0x0000. CRC calculated as 0xC59D is sent with low byte first.

Master Transmit:

<FE> <06> <00> <00> <00> <00> <9D> <C5>

Slave Reply:

<FE> <06> <00> <00> <00> <00> <9D> <C5>

2. Write command to start background calibration. Parameter for background calibration is 6 and for nitrogen calibration is 7. We write command 0x7C with parameter 0x06 to HR2. Starting address is 0x0001 and Register value 0x7C06. CRC calculated as 0xC76C is sent with low byte first.

Master Transmit:

<FE> <06> <00> <01> <7C> <06> <6C> <C7>

Slave Reply:

<FE> <06> <00> <01> <7C> <06> <6C> <C7>

3. Wait at least 2 seconds for standard sensor with 2 sec lamp cycle.

4. Read acknowledgement register. We use function 3 “Read Holding register” to read HR1. Starting address is 0x0000 and Quantity of registers is 0x0001. CRC calculated as 0x0590 is sent with low byte first.

Master Transmit:

<FE> <03> <00> <00> <00> <01> <90> <05>

Slave Reply:

<FE> <03> <02> <00> <20> <AD> <88>

Check that bit 5 (CI6) is 1. It is an acknowledgement of that the sensor has performed the calibration operation. The sensor may skip calibration; an example of a reason for this could be unstable signal due to changing CO<sub>2</sub> concentration at the moment of the calibration request.

## 8.5. Target calibration sequence:

The sensor is addressed as “Any address” (0xFE).

1. Clear acknowledgement register by writing 0 to HR1. Starting address is 0x0000 and Register value 0x0000. CRC calculated as 0xC59D is sent with low byte first.

Master Transmit:

<FE> <06> <00> <00> <00> <00> <9D> <C5>

Slave Reply:

<FE> <06> <00> <00> <00> <00> <9D> <C5>

2. Write target concentration into HR3 register, for example 600 ppm (0x0258 in hexadecimal):

Master Transmit:

<FE> <06> <00> <02> <02> <58> <3C> <9F>

Slave Reply:

<FE> <06> <00> <02> <02> <58> <3C> <9F>

3. Write command to start target calibration. Parameter for target calibration is 5. We write command 0x7C with parameter 0x05 to HR2. Starting address is 0x0001 and Register value 0x7C05. CRC calculated as 0xC62C is sent with low byte first.

Master Transmit:

<FE> <06> <00> <01> <7C> <05> <2C> <C6>

Slave Reply:

<FE> <06> <00> <01> <7C> <05> <2C> <C6>

4. Wait at least 2 seconds for standard sensor with 2 sec lamp cycle.

5. Read acknowledgement register. We use function 3 “Read Holding register” to read HR1. Starting address is 0x0000 and Quantity of registers is 0x0001. CRC calculated as 0x0590 is sent with low byte first.

Master Transmit:

<FE> <03> <00> <00> <00> <01> <90> <05>

Slave Reply:

<FE> <03> <02> <00> <10> <AD> <9C>

Check that bit 4 (CI5) is 1. It is an acknowledgement of that the sensor has performed the calibration operation. The sensor may skip calibration; an example of a reason for this could be unstable signal due to changing CO<sub>2</sub> concentration at the moment of the calibration request.

## 8.6. Read ABC parameter, ABC PERIOD:

One of the ABC parameters, ABC PERIOD, is available for modification as it is mapped as a holding register. This example shows how to read ABC PERIOD by accessing HR32.

The sensor is addressed as "Any address" (0xFE).

Read current setting of ABC PERIOD by reading HR32. We use function code 03 "Read Holding registers". Starting address is 0x001f and Quantity of Registers 0x0001. CRC calculated as 0xC3A1 is sent with low byte first.

Master Transmit:

<FE> <03> <00> <1F> <00> <01> <A1> <C3>

Slave Reply:

<FE> <03> <02> <00> <B4> <AC> <27>

In the slave reply we can see:

Address = 0xFE

Function code = 0x03

Byte count = 0x02

Register value = 0x00B4

CRC = 0x27AC

- We read 2 bytes (1 register of 16 bits)

- 0xB4 hexadecimal = 180 decimal;

180 hours / 24 equals 7.5 days.

- CRC sent with low byte first

## 8.7. Disable ABC function:

Disable the ABC function by setting ABC PERIOD to 0.

The sensor is addressed as "Any address" (0xFE).

Function code 06 "Write Single Register" is used to write to HR32. Register address is 0x001F, register value 0x0000. CRC calculated as 0x03AC is sent with low byte first.

Master transmit:

<FE> <06> <00> <1F> <00> <00> <AC> <03>

Slave reply:

<FE> <06> <00> <1F> <00> <00> <AC> <03>

The reply can be seen as an echo of the transmitted sequence.

## 8.8. Enable ABC function:

Enable the ABC function by setting ABC PERIOD to any value except 0. Set to 7.5 days in this example.

The sensor is addressed as "Any address" (0xFE).

Function code 06 "Write Single Registers" is used to write to HR32. Register address is 0x001f, register value 0x00B4 (7.5 days x 24 hours = 180<sub>10</sub>; 180<sub>10</sub> = 0xB4<sub>16</sub>).

CRC calculated as 0x74AC is sent with low byte first.

Master transmit:

<FE> <06> <00> <1F> <00> <B4> <AC> <74>

Slave reply:

<FE> <06> <00> <1F> <00> <B4> <AC> <74>

The reply can be seen as an echo of the transmitted sequence.

## 8.9. Change Modbus address:

To change sensor's Modbus address, write correct Modbus address into HR20 register and restart sensor.

The sensor is addressed as "Any address" (0xFE), address to set is 0x21:

Master transmit:

<FE> <06> <00> <13> <00> <21> <AC> <18>

Slave reply:

<FE> <06> <00> <13> <00> <21> <AC> <18>

Apply new setting by restarting sensor using power-off/power-on sequence.

## 8.10. Set current pressure:

If host system has information about environment pressure it can be used to enable pressure compensation in sensor's concentration reading. Write current pressure value into HR4 register.

The sensor is addressed as "Any address" (0xFE), pressure value set is 1013.1 hPa (10311 in 0.1 hPa, which is 0x2793 in hexadecimal):

Master transmit:

<FE> <06> <00> <03> <27> <93> <36> <58>

Slave reply:

<FE> <06> <00> <03> <27> <93> <36> <58>

Note: For consistent concentration filtering, pressure value shall be written before or just after first measurement of the sensor after power-up/reset. If this rule could not be applied, the host system shall take in consideration possible delay in change of concentration reading due to pressure compensation due to filtering.

## 8.11. Set default pressure:

If the sensor is used at high altitude and host system has no possibility to write current pressure into the sensor (or host system is absent), it is possible to enable static pressure compensation which sensor will load at every power-on/reset conditions. Write static pressure value into HR27 register.

The sensor is addressed as "Any address" (0xFE), static pressure value set is 1013.1 hPa (10311 in 0.1 hPa, which is 0x2793 in hexadecimal):

Master transmit:

<FE> <06> <00> <1A> <27> <93> <E7> <9F>

Slave reply:

<FE> <06> <00> <1A> <27> <93> <E7> <9F>

The static pressure value will be loaded into HR4 register at next sensor power-up/reset cycle.

## 8.12. Change filter configuration:

To disable filter for concentration, write 0 into HR28:

Master transmit:

<FE> <06> <00> <1B> <00> <00> <ED> <C2>

Slave reply:

<FE> <06> <00> <1B> <00> <00> <ED> <C2>

To restore default filtering parameters write 0xFF into HR28:

Master transmit:

<FE> <06> <00> <1B> <00> <FF> <AD> <82>

Slave reply:

<FE> <06> <00> <1B> <00> <FF> <AD> <82>

## 9. Appendix B: Understanding Output configuration

Senseair S88 has several different output possibilities and can be configured with both software and hardware. In terms of software, the output can be either PWM or digital high/low. Through hardware configuration, the PWM signal can be translated to a voltage or a current output. The following parameters can be configured in software:

MaxLimit – Max output duty cycle (100% = 1023= 0x03FF)

MinLimit – Min output duty cycle (0% = 0 = 0x00)

RDB – Regulator dead band

PRC – Proportional regulator constant

SB1 – ShapeBit1, RDB high bit – mirror in y-axis

SB2 – ShapeBit2, PRC high bit – mirror in x-axis

Offset – X-axis offset (100% = 1023= 0x03FF)

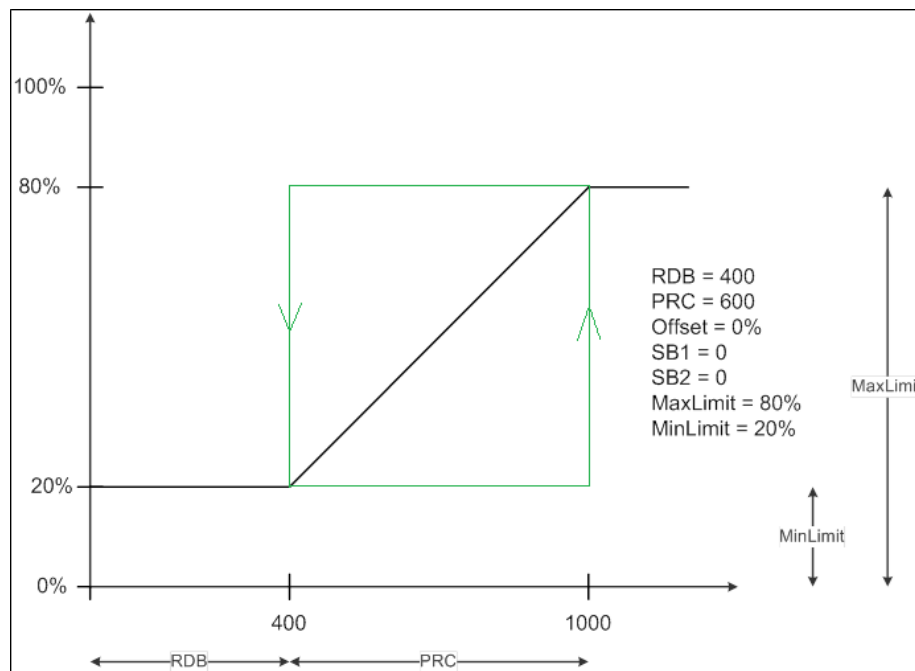

For PWM output (OUT0), the duty cycle will increase from MinLimit to HighLimit linearly when the measured concentration exceeds RDB and is below RDB + PRC.

For Alarm output (OUT1), the output pin will go high when measured concentration is larger than RDB + PRC and return to low when measured concentration is lower than RDB. This mode disregards MinLimit and MaxLimit.

Offset and ShapeBits can be used to mirror behavior.

Configuration examples can be seen below:

Green lines shows behavior of the digital output, black lines show PWM duty cycle output.

Example 1

Example 2
